

Spatial distribution of stable panel sensors

The final stable panel contains 77 sensor-location pairs with broad, but uneven, coverage across Sofia. Most are concentrated in the central, western and southern districts, with observations located both within and outside the nine districts covered by the residential-heating LEZ. The northern and outer parts of the municipality remain sparsely represented. The panel therefore captures different parts of Sofia's urban area, but cannot be considered spatially representative of the municipality as a whole.

Within the districts covered by the LEZ, the retained sensor-location pairs are also unevenly distributed. They appear more concentrated in the southwestern and southern districts, while the northern LEZ districts contain fewer locations.

Administrative boundaries: SofiaPlan (2017); candidate sensor locations: BGAir/FILTER and Sensor.Community.
